You may not be thinking much about device names for your phone, computer and other electronics. After all, whether you leave a name like HP-8910245 or change it to I'm So Awesome doesn't affect its performance. However, using good device names can lead to better organization, performance, or even just enjoyment. Let's consider some tips for coming up with names for devices, including some strategies to avoid.

1. Don't leave the default names before we look at some do and don't make ideas for the name of the device, we need to get one important point aside: you don't have to use default names for your devices. Most devices ship with common names like LENOVO-97FPM91 or Samsung Device. While the default names can be passable, if you only have one or two devices on your network, they're not scalable. Trying to track a dozen or more devices, especially if you have more than one of the same manufacturer, is a huge hassle. The best device titles definitely define what they are, so you don't have to play guessing.
2. Don't use unusual characters While you may be tempted to use characters that are not part of the normal alphabet when coming up with interesting names for your devices, you should stick to a standard set of characters for the best results. Using characters from other languages, emoticons, rare characters or similar can lead to problems in the future. Even if your device's operating system displays the name properly, other devices that you connect it to may have problems with those characters. Bluetooth devices, network-sharing services, and some protocols may opt out because of the name. This is especially true of older systems. For best results, you should also avoid gaps and most characters (such as slash and percentage marks) that don't play well with some operating systems. Stick to letters, numbers and hyphens.
3. Keep names short and simple While long funny names like Destromicon, Epic Annihilator of all people can give you a chuckle at first, you should avoid them. As we've discussed so far, device names often come into play in the context of networks. Having to type long names all the time or worry about them getting cut off in displays will quickly become annoying. Similarly, you don't have to make device names difficult to spell. You don't want to double-check the spelling of Onomatopoeic Thecodontosaurus when you try to remotely connect to it. And if you ever give someone your computer name, you'll sound silly laying out something long and confusing. A short and short computer title will benefit anyone who comes into contact with it. If in doubt, don't use names you didn't like say Google Assistant or Alexa all the time.
4. Use the owner's name as a simple but practical solution for naming your devices is to use the name of whoever it belongs to. For example, you might have Bill-Desktop, Amy-iPad and Julie-Kindle. While it's not particularly interesting, it's and clearly looking at all the devices in your network. Also, compared to some of the other naming ideas that we'll be looking at, device owners don't usually change often. While you can move your computer from one room to another, you probably won't reassign the owner of the device. Using a name can also help differentiate if multiple people in your home own similar devices like Bluetooth speaker or headphones. You don't want to accidentally connect to your roommate's headphones when you're trying to play music.
5. Use the location of the device Another simple naming scheme, especially if you don't have multiple people in your home, is to assign the names of the devices depending on their location. Examples include Kitchen-Speaker, Den Laptop, and Bedroom-Chromecast. This will come in handy if you have multiple units of the same device as a streaming stick or Wi-Fi extension cord. It doesn't make much sense for something like a laptop or phone that moves around regularly. They should apply another naming convention.
6. Use name templates If you don't like any of the super-practical solutions above, you can still come up with interesting device names that don't get upset in use. One easy way to do this is to stick to a template with your devices. The best for your use will depend on your needs and what is memorable, but you'll find a few examples below: Names of planets in the solar system phonetic alphabet (Alpha, Bravo, Charlie, etc.) in a sequence of Names of Ancient Gods from Mythology like Hermes, Poseidon, and Athena Character Names from Your Favorite TV Show, Movie, or Video Game Series Of Insect Species, Birds, or Other Animal Elements of the City that you would like to visit These are just a few examples of many you could use. Choose something that makes sense to you and consider combining one of the above schemes with a more practical device name. For example, you could have a Helium iPhone and a zinc Kindle instead of just Helium and zinc.
7. Get help from a name generator If you are really struggling with naming a phone or other device, you can get some help with online name generators. They will help you make unique names for your devices without any hard work. Naming the Scheme is a great resource for this. The site contains hundreds of categories such as soda brands, the seas of the world, and the names of baby animals. Most of them are scalable, allowing you to go back to the page when you add a new device. The Seventh Sanctuary is another resource for naming generation. Select a category such as technology, symbols, names, and names, and then select a specific type of generator in that category. Some are asking for several pieces at the entrance, while just generate names right away. After a few rounds of generation, you are sure to find something that works. Unique names for each device We have considered several ways to come up with good names for your devices. Of course it doesn't make sense to use it all at the same time Try which ones make sense for your installation---s can always change them in the future. For most people, the combination of the device owner and location will work well. But if you want to get more creative, you have several ways to do this while maintaining a common theme. For more naming fun, check out the best funny Wi-Fi names to give your neighbors a laugh.

7 Best Noise-Cancel Earbuds Noise Cancellation Headphones help block distractions around you. Here are the best noise-cancelling headphones available today. About author Ben Stegner (1565 Articles Published) More from Ben Stegner Do you get a USB device not recognized as a bug whenever you plug in a USB mouse, keyboard, camera or other device? I can't live without USB ports and currently have 5 ports on my computer so I can connect my mouse, keyboard, camera, phone and printer to it all at once! For those of you with even more USB gadgets, you'll probably connect a USB hub to one of your USB ports, so you can connect even more devices. Most of the time it works great, but sometimes your computer can stop recognizing USB DEVICES. The strange thing about this error is that the ports work just fine as I was able to still charge my mobile phone without problems but couldn't get my camera recognized using the same port. After spending a lot of time and trying a bunch of different ways to solve this problem, the only one solution will end up working for me. I will mention that solution first, but will also mention other possible solutions as the first solution may not solve the problem for everyone. Also, check out our YouTube videos if your USB drive doesn't show up on your Windows computer. Method 1 - Turn off your computer so how did I finally solve this problem? Well, if you're lucky, it's a super simple solution! Try this method first, and if it works, you will save a lot of time. Just disconnect the computer from the power supply. Yes, that's it! Note that this doesn't mean just turning off your computer with a power button, because most modern computers don't actually turn off completely and the motherboard will still get power. This is useful sometimes if you want to remotely wake up your computer, etc. Sometimes the motherboard has to be rebooted because things can go wrong, meaning all or some USB ports suddenly stop working. A small microprocessor on the motherboard will reboot the drivers and your USB ports will hopefully be recognising the device again. So first turn off your computer with the Shut Down option in Windows or pressing the power button, and then disconnect your computer from the outlet. Let it sit for a few minutes and then plug it in Inch Method 2 - Driver of the Device Update If Windows is unable to recognize the device, you can also see in the device manager that the device appears as an unknown device. You can get to the device manager by clicking on on and entering devmgmt.msc or going to the control panel and clicking on the manager's device. In this case, you have to press the right button on an unknown device, click on the Properties, then tab the Driver, and then press the Update Driver. If this doesn't work, you can also try to download a driver for your device from the manufacturer's website. If a USB device is just a flash drive, then it's probably not a driver's problem. However, if you install a

USB printer, drawing pad, etc., then it may be worth downloading the driver for that particular device. Method 3 - Reboot and disable USB devices The next thing you can try is to disable all USB devices and then restart the machine. Once you restart, try plugging in the USB device that caused the problem. If this particular USB port doesn't recognize it, try another one. If the device is recognized by another USB port, there may be a hardware problem with one of the USB ports. If no USB port recognizes the device, keep reading because it's probably something else. Method 4 - USB Root Hub Another thing you can try is to open the device manager, expand USB Serial Bus controllers, right click on USB Root Hub and then click on the properties. Click on the Power Management tab and don't let your computer turn off that device to save the power box. If there's more than one USB Root hub on the list, you'll need to repeat these steps for each of them. Click OK and then restart the computer. Try plugging in a USB device and see if it's recognized. If not, go back to the power management tab for each one and check the box again. If it recognizes the device, then leave them unattended. Method 5 - Connect directly to the PC my friend encountered this problem and the reason is eventually his USB hub. He only had three USB ports on his computer, so he bought a hub where he could connect an extra 8 USB devices. I guess this proved too much for his computer and it just started sporadically not recognizing the various devices. After removing the hub and connecting the device directly to the computer, it worked just fine. We couldn't find any other solution to this problem than reducing the number of items connected to the hub. In fact, another solution worked, but it meant you needed to buy a new USB hub with more power. If you're having problems with Windows 8 or Windows 8.1, then you may be in luck. Microsoft has released a fix for Windows 8 without detecting USB devices properly. Make sure to install this hotfix when you start Windows 8. Method 6 - USB Troubleshooter If nothing has worked so far, you can download the Windows USB Troubleshooter Fixit tool. It's a free tool that works with Windows XP, Vista and You can either have troubleshooting fix problems for you or choose fixes yourself. I would just allow it to lock them for you since choices can sometimes be confusing and technical for a novice user. Method 7 - Update Shared USB Hub If You Get Unknown Unknown error in the device manager, you can also try one more thing. Open the device manager and then expand the universal controllers of the serial buses. You should see at least one item called the Common USB Hub. On some computers you can see two, three or more of them. Click the right button on the first and select the software driver update. When the conversation update pops up, choose to view my computer for the software driver. Then click on Let me choose from a list of device drivers on my computer at the bottom. From the list, choose generic USB Hub. Normally, there will be nothing else listed except for this one choice. Click on and then click Close as soon as it finishes installing it. At this point, the device manager's screen must be updated and either the unknown device will still be there or it can be recognized. If it still shows as not recognized, then you repeat the process for each generic USB hub in the list. Method 8 - Remove the USB device as a last resort, you can also try removing all USB devices from your system and then rebooting. I mention this last butt because although Windows has to automatically recognize USB controllers, hubs and devices automatically, sometimes it can fail and you end up without USB ports running. I had a computer with 6 USB ports and only one port would not work properly. I uninstalled everything under USB Serial bus controllers in the manager's device and restarted. Instead of re-discovering everything, I was left without a USB port running, so be careful when using this method. Go to the device manager and start installing each item from under the USB Serial Bus Controllers. Before you start with anything that already works, remove items with exclamation points or that are listed as an Unknown Device. Method 9 - Remove hidden devices by default, the device manager does not show all the devices that have been installed in the system. This basically shows only those that are currently connected. However, if you installed a USB printer before and now no longer use it, it will still be installed but will not appear in the device manager. Some hidden or ghostly USB devices can cause conflicts with modern USB devices and therefore lead to this error. You can view hidden devices in device manager, first opening the command query and then typing the following two commands: set DEVMGR_SHOW_DETAILS=1 DEVMGR_SHOW_NONPRESENT_DEVICES=1 start devmgmt.msc After downloading the device manager, you need to click on View, and then click on Show Hidden Devices. Now you want to expand Imaging devices, universal serial buses and unknown devices. If you see anything listed there that gray or that says an unknown device, go ahead and right click on them and choose Uninstall. We hope that the removal of old devices will allow new devices to work properly. Other possible solutions If nothing worked up to this point, it is pretty safe to say that there may be a problem with the actual equipment. The best thing to do is to connect the device to another other and see if it works or not. If not, it's definitely a problem with the device. Possible solutions #1 - Other possible solutions are to try another USB cable if you have one lying around. If not, just buy a new cheap USB cable from Amazon: from A to B, from A to Micro B, from A to Mini B or from A to A. This is a pretty rare problem, but I've seen it happen several times over the years doing technical support. Possible Solution 2 - Another possible solution is to take the device, connect it to another machine, and if it recognizes the device properly, then extract it properly from that computer before connecting it to the original computer. I've seen this problem happen with several flash drives that have been disabled without ejection properly. After connecting them to another computer and throwing them out properly, they suddenly started appearing on the original computer, which did not recognize them. Possible solutions #3 - Several people have had the good fortune to get rid of this problem by updating BIOS. I've already written an article about whether it's a good idea or not to upgrade bios, but in this case, it might be worth a try. You can also go to BIOS and disable USB, restart your computer and then turn on THE USB again. The only thing you need to make sure that you have a PS2 port on your computer, otherwise you won't be able to do anything once you disable USB in BIOS, if your keyboard and mouse are connected via USB. Hopefully, one of the many solutions above will solve your USB problem. If not, post a comment and I'll try to help. Enjoy! Enjoy! usb video device driver windows 10. usb video device class. usb video device not working. usb video device driver dell. usb video device driver hp. usb video device windows 10. usb video device class mac. usb video device driver usb to vga
